LABORATORY ACTIVITY #4 ASCII Symbol Visualizer

Design and implement a Python program that prompts the user to input a **sentence** and a **display symbol** (a single character). The program will analyze the sentence character by character, calculate a unique numeric value for each character based on its **ASCII value**, and print a horizontal bar of repeating symbols matching that calculated value.

Requirements:

1. **Inputs:** A text string (sentence) and a single-character string (symbol).
2. **Modulo Formula:** Convert each character to its ASCII value and apply **modulo 15** ($\text{ascii_value} \% 15$) to determine the symbol count.
3. **Zero Boundary Handling:** If the modulo operation results in 0, the count must automatically scale up to **15** to ensure every character displays at least some symbols.

Code:

```
ascii.py > ...
1 sentence = input("Enter a sentence: ")
2 symbol = input("Enter the symbol or character to display: ")
3
4 print("--- Output ---")
5
6 for character in sentence:
7     count = ord(character) % 15
8     if count == 0:
9         count = 15
10    print(f"'{character}' (Count: {count:2}) -> {symbol * count}")
```

Output:

```
PS C:\Users\Jonh Orada\Documents> py ascii.py
Enter a sentence: hello
Enter the symbol or character to display: *
--- Output ---
'h' (Count: 14) -> *****
'e' (Count: 11) -> *****
'l' (Count: 3) -> ***
'l' (Count: 3) -> ***
'o' (Count: 6) -> *****
```
